# Diagnosis and Management of Cervical Insufficiency

## Definition and Introduction

Cervical insufficiency is defined as the inability of the uterine cervix to retain a pregnancy in the second trimester, in the absence of uterine contractions.\(^1\)

A history of cervical insufficiency has been applied to women with one or more second trimester pregnancy losses/preterm births (before 34 weeks) who fulfil this definition. It must be noted that a short cervical length on transvaginal scan in the second trimester is a risk factor for preterm birth but is not sufficient to diagnose cervical insufficiency.

Prematurity is the leading cause of perinatal death and disability. Evidence suggests that the incidence of preterm labour and birth is continuing to rise worldwide. Currently 6% of babies in New Zealand are born preterm. Despite efforts and interventions aimed at reducing the incidence globally the results have been largely disappointing.\(^2\)

It can be difficult to distinguish between women who have a short cervix and those that have true cervical insufficiency.

## Risk Factors

Refer to the Obstetric clinic is guided by Section 88 Referral Guideline.

### Cervical Risk Factors: (See Appendix A)

- **Collagen abnormalities** — genetic disorders affecting collagen (e.g., Ehlers Danlos syndrome) have been associated with an increased risk of preterm birth\(^4\)
- **Uterine anomalies** — increase the risk of second trimester preterm birth, e.g. Septate uterus, bicornuate uterus and even arcuate uterus\(^5\).
- **Biologic variation** — although a short cervix is predictive of preterm birth, it is not diagnostic of cervical insufficiency and many women who have a congenitally short cervix deliver at term\(^6\)

### Past Obstetric History: (See Appendix B)

- Recurrent mid-trimester pregnancy losses
- Previous preterm pre-labour rupture of membranes at less than 32 weeks
- Prior pregnancy with a cervical length measurement of less than 25 mm prior to 27 weeks of gestation\(^3\)
ACQUIRED FACTORS (MORE COMMON)

- **Cervical trauma** — may weaken the cervix, and contribute to cervical insufficiency.

- **Mechanical dilation** — eg. dilation and curettage [D&C], dilation and evacuation [D&E], pregnancy termination, hysteroscopy. \(^{7,8}\) In women with a short cervical length and no prior preterm birth, prior cervical mechanical dilatation is one of the most common associated risk factors.

- **Treatment of cervical intraepithelial neoplasia** — LEEP may increase the risk for late preterm birth (from 34 to < 37 weeks of gestation) \(^9\).

- Women may have no symptoms or can present with mild symptoms, eg. painless vaginal spotting, increased vaginal discharge, premenstrual-like cramping or backache or pelvic pressure

- Women may present with these symptoms from as early as 14 to 20 weeks of gestation.

**DIAGNOSIS**

This is either based on history alone or in combination with transvaginal ultrasound (TVU) measurement of cervical length.

**Important note:**
The diagnosis of cervical insufficiency is usually limited to singleton gestations because the pathogenesis of delivery at 14 to 28 weeks in multiple gestations is usually unrelated to a weakened cervix.

**MANAGEMENT**

The management of these women can be divided into two main groups:

1. Women for whom a conservative path will be pursued
2. Women where it is clear that surgical intervention in the form of a cerclage is indicated. This may be either prophylactic or therapeutic.

**APPROACH TO MANAGEMENT**

See pathways below.

APPENDIX A  CONSERVATIVE MANAGEMENT

Women with cervical risk factors for cervical insufficiency but no history of previous loss.

First Obstetric Visit

1. Urine for culture and sensitivity
2. HVS for bacterial vaginosis at first visit
   Any infections should be treated

A single transvaginal cervical length measurement at time of detailed anatomy scan

Cervical length remains > 30 mm
No further scans

Cervical length 25 mm to 29 mm

Cervical length 24 mm
Commence progesterone (complete special authority)
Consider steroids ≥ 24/40*

2 weekly TVS surveillance up until 24 weeks
Any further evidence consider cervical cerclage

Ref.236960

*Discuss with NICU
APPENDIX B CONSERVATIVE MANAGEMENT

Those women with a previous 2nd trimester loss or a previous preterm delivery before 34 weeks

First Obstetric Visit
- Urine for culture and sensitivity
- HVS for bacterial vaginosis at first visit
- Consider progesterone (complete special authority)*
- Any infections should be treated

Request USS for cervical length from 14 weeks at a 2 weekly interval to 24 weeks

Cervical length remains ≥ 25 mm
- Continue two weekly TVS surveillance until 24 weeks gestation

Evidence of shortening ≤ 24 mm on progesterone
- On progesterone
- Not on progesterone
  - Commence progesterone
  - Consider steroids ≥ 24/40
  - If further shortening consider Cervical Cerclage

*Discuss with NICU
APPENDIX C  SURGICAL MANAGEMENT

Suspected history of cervical insufficiency is:

Three or more preterm births < 34 weeks (with progressively earlier deliveries in successive pregnancies) and/or second trimester losses

First Obstetric Visit

1. Urine for culture and sensitivity
2. HVS for bacterial vaginosis at first visit
   Any infections should be treated

History indicated cerclage at 12-14 weeks (after MSS-1 screening)

2 weekly TVS surveillance until 24 weeks gestation

If there is evidence of cervical shortening despite cerclage, consider adding progesterone*
Consider steroids once > 23/40 weeks**

Ref: 236964

**No trials have evaluated the efficiency of combination therapy
*Discuss with NICU
APPENDIX D  ACUTE PRESENTATION WITH SUSPECTED CERVICAL INSUFFICIENCY

History

1. Take an incidental history to rule out infection or preterm labour
2. Maternal Observations → temperature, pulse rate, blood pressure, respiratory rate
3. Examination - abdominal palpitations (fundal height, tenderness, uterine activity)
4. Vaginal assessment - speculum examination of cervical effacement and dilation
   ♦ Exclude SROM, bleeding, abnormal vaginal discharge
5. Digital exam ONLY if evidence of advanced dilation and birth thought imminent
   → consult with senior registrar on-call

Investigations

1. MSU for culture and sensitivity
2. HVS and vulvo-vaginal swab for Chlamydia and Gonorrhoea
3. FBC, CRP
4. If visual signs of dilation and effacement consider a TVS for cervical length and TAS for fetal wellbeing, unless birth imminent

Management

Cervical os fully effaced AND more than 1cm dilated

If no contractions and no signs of infection consider emergency cervical cerclage
Consider steroids depending on gestational age*

If contracting manage as threatened preterm labour

*Discuss with NICU
